Exercise 4.1: Dijkstra's algorithm for finding shortest paths

(a) Draw a directed or undirected graph with at least one negative edge weight for which Dijkstra's algorithm does not find the shortest path from some node s to another node t. Use your example to explain why Dijkstra's algorithm only works on graphs with non-negative edge weights.

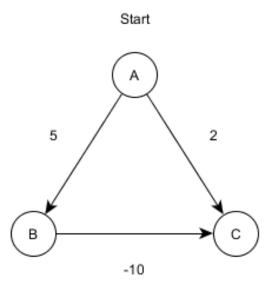

Figure 1: Example directed graph

A-B-C is the shortest path.

We have V = A, B, C, E = (A, C, 2), (A, B, 5), (B, C, -10). So, A-C is found first but not A-B-C. Dijkstra assume that the minimality will never change when "closing" a node. The use of negative numbers change this rule and so is not compatible with Dijkstra.

(b) Dijkstra's algorithm modifications

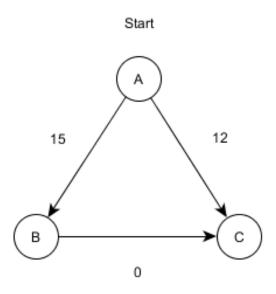

Figure 2: Graph with edge cost ≥ 0 .

We can see that adding 10 to all weights doesn't work. A-C is still the path that Dijkstra find first and in this case, it is the shortest path which was not the case before.

(c) Could BFS be used to find the shortest paths between nodes? If so, what would the edge weights have to look like for BFS to be guaranteed to find the shortest paths between nodes? Why (not)?

With BFS, we can find a path with arbitrary weights but it is not guaranteed to be optimal.

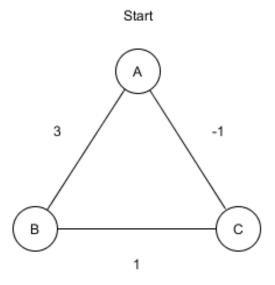

Figure 3: When we want to go from A to B, the shortest path is A - C - B, but with BFS we will first expand A and find the path A-B. When we expand the C node, B is already marked as "duplicate". BFS will ignore the link between B and C in this case.

Exercise 4.2: Force directed layout of networks

(a) Implementation preparation

For the harmonic force we have:

$$F_h(\vec{r}) = -\nabla E_h(\vec{r})$$

According to the definition:

$$\begin{split} &= -\nabla\frac{k}{2} \left\| \vec{r} \right\|^2 = -\frac{k}{2} \nabla \left\| \vec{r} \right\|^2 \\ &= -\frac{k}{2} \nabla (\sqrt{x^2 + y^2 + z^2})^2 \\ &= -\frac{k}{2} \nabla (x^2 + y^2 + z^2) \\ &= -\left(\begin{matrix} kx \\ ky \\ kz \end{matrix} \right) \end{split}$$

For the Coulomb force we have:

$$F_c(\vec{r}) = -\nabla E_c(\vec{r})$$

$$= -\nabla \left(\frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{\|\vec{r}\|}\right)$$

$$= -\nabla \left(\frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{\sqrt{x^2 + y^2 + z^2}}\right)$$

$$= -\frac{q_1 q_2}{4\pi\epsilon_0} \nabla \left(\frac{1}{\sqrt{x^2 + y^2 + z^2}}\right)$$

We apply partial derivatives on $\frac{1}{\sqrt{x^2+y^2+z^2}}$ (chain rule):

$$=-\frac{q1q2}{4\pi\epsilon_0}\begin{pmatrix}-\frac{x}{(x^2+y^2+z^2)^{\frac{3}{2}}}\\-\frac{y}{(x^2+y^2+z^2)^{\frac{3}{2}}}\\-\frac{z}{(x^2+y^2+z^2)^{\frac{3}{2}}}\end{pmatrix}=\frac{q1q2}{4\pi\epsilon_0}\begin{pmatrix}\frac{x}{(x^2+y^2+z^2)^{\frac{3}{2}}}\\\frac{y}{(x^2+y^2+z^2)^{\frac{3}{2}}}\\\frac{z}{(x^2+y^2+z^2)^{\frac{3}{2}}}\end{pmatrix}$$

(b) Adapting the energy equations for networks

For the Harmonic force we have:

$$F_h(\vec{r}_{ij}) = -\nabla E_h(\vec{r}_{i,j}) = -\begin{pmatrix} x_i - y_j \\ y_i - y_j \end{pmatrix}$$

For the Coulomb force:

$$F_c(\vec{r_{ij}}) = k_1 k_2 \left(\frac{\frac{x_i - x_j}{((x_i - x_j)^2 + (y_i - y_j)^2)^{\frac{3}{2}}}}{\frac{y_i - y_j}{((x_i - x_j)^2 + (y_i - y_j)^2)^{\frac{3}{2}}}} \right)$$

(c) Understanding the Coulomb and harmonic energy: How does the Coulomb energy and harmonic energy change if the degree of both nodes is increased or decreased? What happens if the distance between two nodes is increased or decreased?

If the degree of both nodes increases, the harmonic force is not affected but Coulomb force will increase with a factor $-k_1k_2$ as seen in (b).

However, if the distance increase, both Coulomb and harmonic will be affected. The Harmonic energy is $\frac{1}{2}||\vec{r^2}||^2$ and the Coulomb $\frac{k_ik_j}{||\vec{r_{ij}}||}$ so if we increase the distance, Coulomb energy is going to decrease and Harmonic energy to increase.

(d) Understanding the forces: Why is the Coulomb force the repulsive force and the harmonic force the attractive force?

In our case, all the node will have a positive charge (the degree) which means that they are all going to repel each other. However, the objective is to keep connected nodes close to each other and at the same time spread the rest of the graph away to give it a nice display. The Coulomb force is the basic force between every node according to their degrees and distance, disregarding their connection. The Harmonic force is applied here only when two nodes are connected to each other and because it has opposite sign, as seen in (b), it will temper the force between the two connected nodes and allow to keep them close ot each other.

(e) Implementing the force directed layout algorithm

```
Listing 1: layout main.py

(f) Simulated annealing: Explain why simulated annealing is a worthwhile optimisation principle in practice.

Simulated annealing will approximate the global minimum (unlike Gradient descent, which will find a precise local minima). These methods avoid getting stuck in a local minima by making big random jumps in the beginning and reduce their size as we stabilize the layout. If a node is "stuck" in a force-field in which it does not belong,see figure 13, a random force might help it to get out. If a node is already in a good position, this random force might false a little bit the scheme but won't break the overall structure. As the temperature is decreasing, the random force won't have the ability to displace the node far away of their position. The more iterations, the less amount of temperature.

(g) Applying the layout algorithms

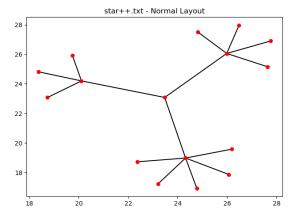

Figure 8:

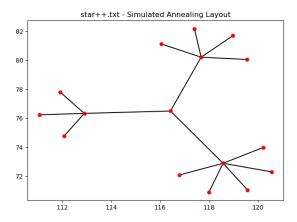

Figure 9:

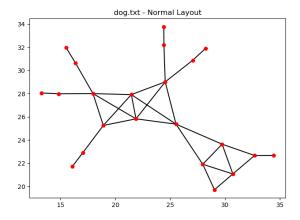

Figure 10:

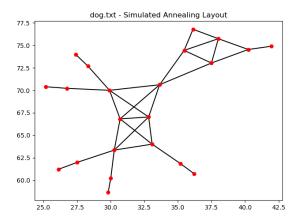

Figure 11:

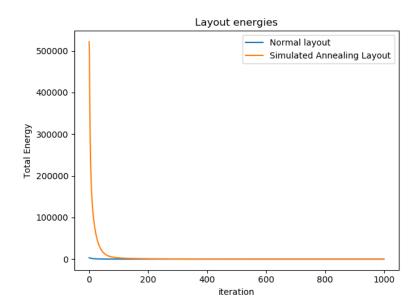

Figure 12: Energies for the star++ graph

We can see in figure 12, the total energy lower quicker with the normal layout than with the Simulated Annealing. Both meet around zero after around 200 iterations.

As said in (f), a node can randomly get stuck somewhere where the forces can't simply make it move and the Simulated Annealing can be useful. In figure 13. After having ran the simulations many times, no such error appeared when using the Simulated Annealing layout.
